About the Editorial Team

Dale Crane (1923–2010) was involved in aviation for more than 50 years. He began his career in the U.S. Navy as a mechanic and flight engineer in PBVs. After World War II, he attended Parks Air College. After college, he worked as an instrument overhaul mechanic, instrument shop manager, and flight test instrumentation engineer. Later he became an instructor and then director of an aviation maintenance school.

Dale was active as a writer of aviation technical materials, and as a consultant in developing aviation training programs. ATEC presented to Dale Crane their special recognition award for “his contribution to the development of aviation technicians as a prolific author of specialized maintenance publications.” He also received the FAA’s Charles Taylor “Master Mechanic” award for his years of service in and contributions to the aviation maintenance industry, and the recognition of his peers for excellence as a leader and educator in aircraft maintenance, and aviation safety advocate.

Keith Anderson is an Associate Professor in the Applied Aviation Science Department in the College of Aviation at LeTourneau University. He obtained his A&P certificate in 1983 and received his Inspection Authorization (IA) rating in 1997. He is a commercial pilot with Instrument Rating and is a certified flight instructor. He has an Associate Degree in Aviation Technology, a Bachelor of Science Degree in Electrical Engineering Technology, Aviation Option from LeTourneau University, and an MBA with Management Certificate from Corban University. He has been employed as a mechanic and director of maintenance at several maintenance facilities, including shops operating under Part 135 and Part 121. In addition to his maintenance experience, he flew for eight years for a non-profit mission organization in Venezuela and Guatemala and additionally served as chief inspector for one year for a non-governmental organization (NGO) in Uganda.

Following his overseas experiences, he was employed as a design engineer, director of engineering, and director of customer service for a company developing a new single-engine turboprop utility airplane, with additional duties as an Administrative Designated Engineering Representative (DER), and he was the primary point of contact with the FAA Aircraft Certification Office for the successful certification of the aircraft.

Keith later became the vice president of engineering for a well-known company that developed supplemental type certificates (STCs) for corporate aircraft and also served as the director of engineering for an aircraft simulation company.

Answers to Chapter 2 Study Questions 52

Why Study Mathematics?

Mathematics is an exact science that gives us the basic language for all technology, and without it, aviation as we know it could not exist. We use mathematics daily for a variety of tasks, from figuring our paycheck to determining the strength of a riveted joint. Algebra is a widely used part of mathematics that uses mathematical symbols and uses rules for manipulating these symbols.

Today, a knowledge of mathematics and algebra are more important than ever before. All aircraft, engines, and the systems they contain must obey the laws of physics, and only by using the tools of mathematics are engineers able to design equipment that follows these laws. And only by understanding and using mathematics and algebra are mechanics able to maintain this equipment so it will continue to function properly. Some of these areas include calculating aircraft weight and balance, figuring out current, resistance, and voltage in a circuit, calculating required torque on a bolt when using an adapter, or determining forces on an object.

The miracle of modern engineering and production is possible only because of computers that quickly and accurately make the vast number of mathematical computations that are needed. Pocket-size calculators help to take the boredom out of mathematics and free the technician to concentrate on the practical use of this science.

In this section, we begin with a review of the number systems commonly used and progress through the four basic procedures in arithmetic, through a discussion of common and decimal fractions, percentage, ratio and proportion, powers and roots, signed numbers, and trigonometry, and conclude with mathematical sequences and practical problems.

To gain the most from this chapter, work all of the study problems by hand and check your answers with a pocket calculator; then check with the answers in the back of this chapter. By practicing the old-fashioned way of working problems, you will sharpen your skills and better understand the mathematical process.

Numerals

Numerals are the symbols used in mathematics to represent values. We are most familiar with the Arabic numerals, but Roman numerals have some special functions.

Arabic Numerals

Practically all modern mathematics are performed with Arabic numerals. This series of ten symbols is thought to have been developed by the Hindus in India and introduced in Europe by the Arabs.

Arabic numerals. The symbols 0, 1, 2, 3, 4, 5, 6, 7, 8, and 9 used to represent values in the decimal number system.

The ten symbols may be arranged in such a way that they represent any quantity we want, and we use Arabic numerals, also called digits, in both the decimal and binary number systems.

The ten Arabic numerals are: 0, 1, 2, 3, 4, 5, 6, 7, 8, and 9.

Roman Numerals

Roman numerals were used in an ancient number system, and are occasionally used as the chapter numbers in some books and on some of the more decorative clock faces. Seven capital letters represent numbers, and combinations of these letters may be used to make up any value we want. Mathematical manipulation of these numerals is too awkward for us even to consider here.

The seven Roman numerals and their Arabic equivalent are seen in Figure 2-1.

Roman	Arabic
I	1
V	5
X	10
L	50
C	100
D	500
M	1,000

Figure 2-1. Comparison of Roman and Arabic numerals.

Number Systems

Decimal System

The number system used every day in aviation maintenance is the decimal system. It is based on the ten Arabic numerals, and we can arrange these ten digits so they represent any value we want. We do this by observing the position the digits occupy in the string of digits. The value of the digits in a decimal number is determined by their placement relative to the decimal point.

The easiest way to understand the decimal system is to use a number line, Figure 2-2. The center of the number line is marked with a small dot similar to a period used in writing. This is called the decimal point or, more generally, just “the decimal.”

1,000,000 100,000 10,000 1,000 100 10 1 (.) .1 .01 .001 .0001 .000 01 .000 001

Figure 2-2. On the number line, all numbers to the left of the decimal point are whole numbers, and all numbers to the right of the decimal point are fractional parts of a whole number.

The digit in the first place to the left of the decimal point has a value between 1 and 9. The digit in the second place has a value between 10 and 90, and the digit in the third place has a value between 100 and 900. This continues on, with each place to the left increasing the value by ten times.

To find the exact value of any number, just add all of the place values to the left of the decimal point. For example, we can break the number 52,496 down as shown in Figure 2-3.

$$\begin{aligned}
 50,000 &= 5 \cdot 10,000 \\
 2,000 &= 2 \cdot 1,000 \\
 400 &= 4 \cdot 100 \\
 90 &= 9 \cdot 10 \\
 \underline{6} &= 6 \cdot 1 \\
 52,496 &
 \end{aligned}$$

Figure 2-3. Place values for numbers greater than 1 in the decimal system.

0.1	=	1/10
0.01	=	1/100
0.001	=	1/1,000
0.000 1	=	1/10,000
0.000 01	=	1/100,000

Figure 2-4. Place values for numbers smaller than 1 in the decimal system

300.	=	3 · 100
40.	=	4 · 10
7.	=	7 · 1
0.6	=	6 · 0.1
0.09	=	9 · 0.01
<hr/>		
347.69		

Figure 2-5. Place values for mixed numbers in the decimal system.

In the United Kingdom, the decimal is placed above the line (·), but in the United States the decimal is placed on the line (.), and the raised dot (·) is used to indicate multiplication. All numbers to the left of the decimal point are numbers greater than 1, and those to the right of the decimal are fractions, or numbers less than 1.

The digit in the first place to the right of the decimal point has a value between $\frac{1}{10}$ and $\frac{9}{10}$, and the digit in the second place has a value between $\frac{1}{100}$ and $\frac{9}{100}$. The value of the digits becomes smaller by a factor of ten for each place the digit is to the right of the decimal point (see Figure 2-4). The number 347.69 can be broken down as we see in Figure 2-5.

For whole numbers greater than 1, the decimal point is normally omitted, and for numbers less than 1, a zero is normally placed before the decimal point.

Binary System

All data used by digital computers is represented with only two electrical conditions, OFF or ON. This can also be LOW or HIGH, or NEGATIVE or POSITIVE. Computers can do many different things when they are commanded by combinations of these two conditions.

To get the most value from digital computers, we must be able to reduce all of the data we use to a series of numbers, and since the computer recognizes only two conditions, we use the binary number system. This system uses only two symbols, 0 and 1. These are called bits (**BI**nary **digIT**s).

Since the binary numbering system uses 1s and 0s, it is referred to as a base 2 numbering system. A base 10 numbering systems counts from 0 to 9, and then starts over. A base 2 numbering system counts from 0 to 1, and then starts over. This counting process is show in Figure 2-6.

As we can see in the counting progression above, in the binary system the value of the bits doubles as they progress from right to left. The values of the first ten bits, reading from right to left, are: 1, 2, 4, 8, 16, 32, 64, 128, 256, and 512, as shown in Figure 2-7.

Number	Binary equivalent
0	0000
1	0001
2	0010
3	0011
4	0100
5	0101

13	1101
14	1110
15	1111
16	10000

Figure 2-6. Base 10 numbers and their binary equivalent.

Decimal	Binary place values										Binary
	512	256	128	64	32	16	8	4	2	1	
1	0	0	0	0	0	0	0	0	0	1	000000001
10	0	0	0	0	0	0	1	0	1	0	000001010
97	0	0	0	1	1	0	0	0	0	1	000110001
152	0	0	1	0	0	1	1	0	0	0	001001100
312	0	1	0	0	1	1	1	0	0	0	010011100
1,000	1	1	1	1	1	0	1	0	0	0	111110100

Figure 2-7. Conversion between the binary and decimal system.

To find the binary equivalent of a decimal number, start with the left side of the chart and subtract the binary place values from the decimal number. Proceeding to the right, every time a place value goes into the decimal number, put a 1 for the place value. When a place value does not go into the decimal number, put a zero for that place value. For example, the binary equivalent of 152 is 10011000:

- $152 - 128 = 24$, so 1 goes in the 128 column
- 64 is greater than 24, so 0 goes in the 64 column
- 32 is greater than 24, so 0 goes in the 32 column
- $24 - 16 = 8$, so 1 goes in the 16 column
- $8 - 8 = 0$, so 1 goes in the 8 column
- There is nothing left, so 0 goes in the 4, 2, and 1 columns

Any zeros to the left of the first 1 may be omitted without changing the value of the binary number.

To find the decimal equivalent of a binary number, add all of the place values in which there is a 1. The decimal equivalent of 0100111000 is 312.

- Start at the right and add the place values in which there is a 1
- $0 + 0 + 0 + 8 + 16 + 32 + 0 + 0 + 256 = 312$

Arithmetic

Arithmetic is essentially the branch of mathematics in which we use addition, subtraction, multiplication, and division to solve problems that may contain positive and negative numbers and zero.

The pocket calculator has just about spoiled us for working arithmetic problems the old-fashioned way, but it is a good idea to review a few principles. Practicing may prevent some common mistakes.

Addition

Addition is the process of finding the combined values of two or more numbers, their sum. The symbol for addition is the plus sign (+).

To find the sum, arrange the numbers in a vertical column with the decimal points all in a line, and combine the values of the numbers in each column. Since most whole numbers are written without a decimal point, just align the numbers with the least significant digits, the digits on the right, all in a straight vertical line. See Figure 2-8.

addition. The process of finding the combined value of two or more numbers.

$$\begin{array}{r} 64 \\ 32 \\ 736 \\ + \quad 9 \\ \hline \end{array}$$

Figure 2-8. Arrangement of numbers for addition.

$$\begin{array}{r}
 12 \\
 64 \\
 32 \\
 736 \\
 + 9 \\
 \hline
 841
 \end{array}$$

Figure 2-9. The process of addition.

sum. The answer in an addition problem.

least significant digit. The digit on the extreme right in a decimal number.

1. Arrange the numbers for addition, and combine the values of all of the digits in the ones column, the column on the right. When all of these digits are added together, they total 21. Twenty-one is 2 tens plus 1 one. Place the 1 below the ones column, and carry the 2 above the tens column. See Figure 2-9.
2. Combine the value of all of the digits in the tens column, including the 2 you just carried. The sum of these four digits is 14. This is 1 hundred, plus 4 tens. Put the 4 below the tens column and carry the 1 at the top of the hundreds column.
3. Now, combine the values of the digits in the hundreds column. This is 7 plus 1, or 8. Place the 8 below the hundreds column, and this gives the sum of the four numbers, which is 841.

The best way to check the accuracy of an addition problem is to add the numbers in a different sequence. If you added them the first time from the top number down, check by adding them from the bottom to the top.

Before leaving addition problems, there is one fact that will help in practical problems: It makes no difference in which order we add numbers.

$$\begin{array}{r}
 6 \quad 4 \quad 4 \\
 4 \quad 19 \quad 5 \\
 19 \quad 5 \quad 6 \\
 + 5 \quad + 6 \quad + 19 \\
 \hline
 34 \quad 34 \quad 34
 \end{array}$$

subtrahend. The number in a subtraction problem that is to be subtracted.

minuend. The quantity in a subtraction problem from which another quantity is to be subtracted.

difference. The amount by which one quantity is greater or less than another. The difference is the answer in a subtraction problem.

$$\begin{array}{r}
 486 \\
 - 32 \\
 \hline
 454
 \end{array}$$

Figure 2-10. This subtraction process does not involve borrowing.

Subtraction

Subtraction is the process of finding the difference between two numbers. The symbol for subtraction is the minus sign (–).

The number you begin with is called the minuend, and the number you subtract, or take away, from this is called the subtrahend. The answer is called the difference.

In Figure 2-10 we find the difference between 486 and 32. Place the subtrahend, 32, under the minuend, 486, with the least significant digits, the right-hand digits, lined up. Find the difference between the values of the digits in the ones column. $6 - 2 = 4$. Place the 4 below the 2 in the ones column.

Find the difference between the values of the digits in the tens column. This is $8 - 3 = 5$. Place the 5 below the tens column.

Since there is no number in the hundreds column of the minuend, just place the 4 in the answer in the hundreds column.

The difference between 486 and 32 is 454.

Some subtraction problems have digits in the subtrahend that are larger than those in the minuend, and we have to do some borrowing.

In Figure 2-11, we see this situation:

- We want to find the difference between 234 and 76.
- Six ones is larger than 4 ones, so we must borrow 10 ones from the 3 in the tens column. This gives us 14 ones, and 6 from 14 leaves 8. Place the 8 in the ones column of the answer.
- Seven is larger than 2, so we must borrow 10 tens from the hundreds column to get 12 tens. Seven from 12 gives us 5 tens in the answer.
- We had to borrow 10 tens, or 1 hundred from the 2 hundreds, so we have 1 left in the hundreds column. Place a 1 in the hundreds column of the answer.

To check a subtraction problem, add the subtrahend to the difference, and if the problem has been worked correctly, the sum will be the same as the minuend.

Multiplication

Multiplication is a process in which one number is added to itself a given number of times.

Various symbols are used to indicate the multiplication process. These are the letter “x,” or a small dot placed in the center of the space “·,” or parentheses. Parentheses are used in problems in which other functions must be applied to terms before they are multiplied.

$$5 \times 8 \times 10 = 400$$

$$5 \cdot 8 \cdot 10 = 400$$

$$(3 + 2)(12 - 4)(6 + 4) = 400$$

The number to be multiplied is called the multiplicand, and the number used to multiply is called the multiplier. The answer is called the product.

The multiplication problem $4 \cdot 3 = 12$ is the same as four added to itself three times: $4 + 4 + 4 = 12$.

When multiplying numbers having more than one digit, the way we arrange them is important. This is shown in Figure 2-12.

- To multiply 365 by 124, begin by multiplying 365 by 4.
 - First, multiply 5 by 4. $5 \cdot 4 = 20$
Place the 0 in the ones column of the answer and carry the 2 above the tens column.
 - Now, multiply 6 tens by 4 and add the 2 tens we carried.
 $4 \cdot 6 = 24 + 2 = 26$ (This is actually $(4 \cdot 60) + 20 = 260$.)
Place the 6 in the tens column of the answer, and carry the 2 (200) above the hundreds column.

<p>A</p> $\begin{array}{r} 12 \\ 234 \\ - 76 \\ \hline \end{array}$	<p>B</p> $\begin{array}{r} 2 \\ 2\cancel{3}(14) \\ - 76 \\ \hline 8 \end{array}$
<p>C</p> $\begin{array}{r} 1(12) \\ 2\cancel{3}4 \\ - 76 \\ \hline 58 \end{array}$	<p>D</p> $\begin{array}{r} 1 \\ 1\cancel{2}34 \\ - 76 \\ \hline 158 \end{array}$

Figure 2-11. This subtraction process does involve borrowing.

<p>A</p> $\begin{array}{r} 22 \\ 365 \\ \times 124 \\ \hline 1460 \end{array}$	<p>B</p> $\begin{array}{r} 11 \\ 365 \\ \times 124 \\ \hline 1460 \\ 730 \end{array}$
<p>C</p> $\begin{array}{r} 365 \\ \times 124 \\ \hline 1460 \\ 730 \\ + 365 \\ \hline 45,260 \end{array}$	

Figure 2-12. The process of multiplication.

multiplicand. The number in a multiplication problem that is multiplied.

multiplier. The number in a multiplication problem by which the other number, the multiplicand, is multiplied.

product. The answer in a multiplication problem.

3. Multiply 3 hundreds by 4, and add the 2 hundreds we carried.

$$4 \cdot 3 = 12 + 2 = 14 \text{ (This is actually } (4 \cdot 300) + 200 = 1400.)$$

Place the 4 in the hundreds column of the answer and the 1 in the thousands column. The answer for our first step is 1,460.

B. The second stage is to multiply 365 by 2 in the tens column (20).

1. Multiply 5 by the 2 in the tens column. $5 \cdot 2 = 10$

$$\text{(This is actually } 5 \cdot 20 = 100.)$$

Place the zero in the tens column and carry the 1 (10) above the tens column.

2. Multiply 6 tens by 2 tens, and add the 10 tens we carried.

$$6 \cdot 2 = 12 + 1 = 13 \text{ (This is actually } (60 \cdot 20) + 100 = 1300.)$$

Place the 3 in the hundreds column and carry the 1 (100) above the hundreds column.

3. Multiply 3 hundreds by 2 tens, and add the 10 hundreds we carried.

$$3 \cdot 2 = 6 + 1 = 7 \text{ (This is actually } (300 \cdot 20) + 1000 = 7000.)$$

Place the 7 in the thousands column.

C. The final stage is to multiply 365 by 1 in the hundreds column (100).

1. Multiply 5 by 1 hundreds. $5 \cdot 1 = 5$ (This is actually $5 \cdot 100 = 500$.)

Place the 5 in the hundreds column.

2. Multiply 6 tens by 1 hundreds. $6 \cdot 1 = 6$

$$\text{(This is actually } 60 \cdot 100 = 6000.)$$

Place the 6 in the thousands column.

3. Multiply 3 hundreds by 1 hundred. $3 \cdot 1 = 3$

$$\text{(This is actually } 300 \cdot 100 = 30,000)$$

Place the 3 in the ten thousands column.

4. Add all the numbers we have just created to get the product of

$$365 \cdot 124 = 45,260.$$

To check a multiplication problem, divide the product by the multiplier, and you should get the multiplicand.

$$45,260 \div 124 = 365$$

In a multiplication problem involving several steps of multiplication, the order in which the numbers are multiplied has no effect in obtaining the correct answer.

$$6 \cdot 5 \cdot 9 \cdot 20 = 5,400$$

$$20 \cdot 5 \cdot 6 \cdot 9 = 5,400$$

$$9 \cdot 6 \cdot 20 \cdot 5 = 5,400$$

$$5 \cdot 20 \cdot 9 \cdot 6 = 5,400$$

Division

Division is the process of determining the number of times one number will go into another. The number to be divided is called the dividend, the number that is to go into the dividend is called the divisor, and the answer is the quotient. The symbols for division are \div , and $/$.

Division can actually be thought of as a series of subtractions. We can find the number of times 7 will go into 56 by subtracting 7 from 56 until we get zero. Seven will go into 56 eight times. See Figure 2-13.

If the divisor does not go into the dividend an even number of times, the number left over is called the remainder.

$$42 \div 5 = 8, \text{ remainder } 2$$

Long division is the term we generally use when the divisor has two or more digits. To solve a long division problem, we arrange it as we see in Figure 2-14.

1. Place the dividend under the division sign, and the divisor to the left of it.

The 24 of the divisor will go into 136 of the dividend 5 times, with some remainder. Place the 5 above the 6. Multiply the 24 by 5, to get 120. Place the 120 below the 136.

Subtract 120 from 136 to get 16 as the remainder for our first step.

2. Bring the 8 from the dividend down and place it after the remainder to give us a new dividend of 168.

The 24 of the divisor will go into the new dividend 7 times. Place the 7 above the 8 and multiply the 24 by 7. Place the product of 168 below the new dividend and subtract. Since there is no difference, there is no remainder in this problem.

Twenty-four will go into 1,368 fifty-seven times.

Division problems may be written in any of the ways we see in Figure 2-15.

dividend. The quantity in a division problem that is divided.

divisor. The quantity in a division problem by which the dividend is divided.

quotient. The answer in a division problem.

remainder. The number left in a division problem when the divisor does not go into the dividend an even number of times.

$$\begin{array}{r} 56 - 7 = 49 \quad (1) \\ 49 - 7 = 42 \quad (2) \\ 42 - 7 = 35 \quad (3) \\ 35 - 7 = 28 \quad (4) \\ 28 - 7 = 21 \quad (5) \\ 21 - 7 = 14 \quad (6) \\ 14 - 7 = 7 \quad (7) \\ 7 - 7 = 0 \quad (8) \end{array}$$

Figure 2-13. Division is actually a series of subtractions. $56 \div 7 = 8$

$$\begin{array}{r} 57 \\ 24 \overline{)1368} \\ \underline{120} \\ 168 \\ \underline{168} \\ 000 \end{array}$$

Figure 2-14. The process of long division

$$24 \overline{)1368} \quad \text{or} \quad 1368 \div 24 \quad \text{or} \quad \frac{1368}{24}$$

Figure 2-15. Ways of writing division problems.

STUDY QUESTIONS: ARITHMETIC

Work all of these problems by hand, and then you may check your accuracy with a calculator.

Answers are provided on page 52.

1. Find the sum of each of these columns of numbers:

a. 321	b. 65	c. 7	d. 936
66	681	47	72
59	6385	371	7931
<u>6</u>	<u>83</u>	<u>849</u>	<u>365</u>

2. Find the difference between each of these numbers:

a. 458	b. 756	c. 5296	d. 39
<u>196</u>	<u>47</u>	<u>4805</u>	<u>18</u>

3. Find the product in each of these multiplication problems:

a. 248	b. 1969	c. 306	d. 9841
<u>62</u>	<u>142</u>	<u>212</u>	<u>77</u>

4. Find the quotient and remainder of each of these division problems:

a. $3685 \div 92 =$	_____	remainder	_____
b. $5694 \div 23 =$	_____	remainder	_____
c. $148 \div 53 =$	_____	remainder	_____
d. $98 \div 7 =$	_____	remainder	_____

Fractions

fraction. The mathematical term that denotes a whole is divided into several parts, and the number of the parts is identified.

Up to this point, we have been working with whole numbers, but now we want to see how to work with only parts of a number. These parts are called fractions. There are two kinds of fractions: common fractions, in which the whole number can be divided into any number of parts, and decimal fractions, in which the whole number may be divided only by numbers that are multiples of 10.

common fraction. A fraction written in the form of one number above another. The number on the bottom is the denominator, indicating the number of parts into which the whole is divided, and the top number is the numerator indicating the number of parts being considered.

Common Fractions

A common fraction is written as two numbers, one above the other, or if the numbers are all on the same line, they are divided by a slash mark. Examples of common fractions are $\frac{1}{2}$, $\frac{3}{8}$ and $\frac{15}{64}$.

General

Fifth Edition

Also in the Aviation Mechanic Series

Airframe Systems

Airframe Structures

Powerplant

General, the first book in Dale Crane's four-part Aviation Mechanic Series, introduces students to the aviation industry and its history, mathematics, and basic electricity and its application in airplanes. This textbook goes on to cover advanced topics outlined in the FAA test standards for aviation mechanics such as aircraft hardware, materials, weight and balance, servicing, troubleshooting, human factors, regulations, and more. Recent innovations in batteries and alternative fuels are also included. This text meets FAA aviation maintenance technician school curriculum requirements and prepares applicants for all subjects tested on the General FAA Knowledge Exam.

This new fifth edition features updated content reflecting new regulations and changes affecting aviation mechanic certification. Originally written by Dale Crane in 1993, this textbook has been reviewed and updated by an editorial team consisting of aviation mechanics, university professors, and pilots.

ASA's Aviation Mechanic Series is a current, comprehensive, and effective learning resource for aviation mechanic training. Designed for use in classrooms and for independent study, these textbooks feature color figures, study questions with answer keys, and extensive glossaries and indexes.
